

The four-line prompt.

Every prompt in today's session is these four lines, in a different order, with a different file attached. Keep this card.

1 The role and the decision

What job it is doing, and what you are deciding. Not "analyse my sales".

You are helping me plan next month's production at a craft brewery.

2 The evidence, attached

Attach the file first. Never describe your numbers in words and hope it imagines them.

Attached are 18 months of taproom sales, brew records and the beer master list.

3 The shape you want back

Name the columns, the order, and the length. This is the line that stops the essay.

Give me a table: beer, batches, litres, reason. Ranked. No commentary.

4 The honesty clause

Without it, the model fills a gap rather than admitting to one.

Tell me which numbers are thin instead of guessing.

On your own file: your column names will not match. Add one line and it maps the rest. "In my file, litres sold is called Qty_Ltr and the date column is TxnDate."

THE WHOLE THING, READY TO PASTE

You are helping me plan next month's production at a craft brewery.

Attached are 18 months of taproom sales, brew records and the beer master list.

Work out, for each beer: litres sold per month, the trend over the last six months, and how many batches I need next month to cover demand plus three weeks of cover.

Give me the answer as a table: beer, batches, litres, reason. Ranked. No commentary.

Tell me which numbers you are confident in and which are thin. If the history for a beer is too short or too seasonal to forecast, say so instead of guessing.
